For complex search tasks, for example question answering retrieval, the search

can significantly be improved by using \*\*Retrieve & Re-Rank\*\*.

## Retrieve & Re-Rank Pipelineïf•

The following pipeline for Information Retrieval / Question Answering Retrieval works very well. All components are provided and explained in this article:

![InformationRetrieval](https://raw.githubusercontent.com/UKPLab/sentencetransformers/master/docs/img/InformationRetrieval.png)

Given a search query, we first use a \*\*retrieval system\*\* that retrieves a large list of e.g. 100 possible hits which are potentially relevant for the guery. For the retrieval, we can use either lexical search, e.g. with a vector engine like Elasticsearch, or we can use dense retrieval with a bi-encoder. However, the retrieval system might retrieve documents that are not that relevant for the search query. Hence, in a second stage, we use a \*\*reranker\*\* based on a \*\*cross-encoder\*\* that scores the relevancy of all candidates for the given search query. The output will be a ranked list of hits we can present to the user.

## Retrieval: Bi-Encoderïf•

For the retrieval of the candidate set, we can either use lexical search (e.g. [Elasticsearch](https://www.elastic.co/elasticsearch/)), or we can use a biencoder which is implemented in Sentence Transformers.

Lexical search looks for literal matches of the guery words in your document

collection. It will not recognize synonyms, acronyms or spelling variations.

In contrast, semantic search (or dense retrieval) encodes the search query

into vector space and retrieves the document embeddings that are close in

vector space.

![SemanticSearch](https://raw.githubusercontent.com/UKPLab/sentence-

transformers/master/docs/img/SemanticSearch.png)

Semantic search overcomes the shortcomings of lexical search and can recognize

synonym and acronyms. Have a look at the [semantic search

article](../semantic-search/README.html) for different options to implement

semantic search.

## Re-Ranker: Cross-Encoderïf•

The retriever has to be efficient for large document collections with millions

of entries. However, it might return irrelevant candidates. A re-ranker based

on a Cross-Encoder can substantially improve the final results for the user.

The guery and a possible document is passed simultaneously to transformer

network, which then outputs a single score between 0 and 1 indicating how

relevant the document is for the given query.

![CrossEncoder](https://raw.githubusercontent.com/UKPLab/sentence-

transformers/master/docs/img/CrossEncoder.png)

The advantage of Cross-Encoders is the higher performance, as they perform

attention across the query and the document. Scoring thousands or millions of (query, document)-pairs would be rather slow. Hence, we use the retriever to create a set of e.g. 100 possible candidates which are then re-ranked by the Cross-Encoder.

## Example Scriptsïf•

\*

\*\*[retrieve\_rerank\_simple\_wikipedia.ipynb](https://github.com/UKPLab/sentence-transformers/tree/master/examples/applications/retrieve\_rerank/retrieve\_rerank\_simple\_wikipedia.ipynb)\*\* [ [Colab Version](https://colab.research.google.com/github/UKPLab/sentence-transformers/blob/master/examples/applications/retrieve\_rerank/retrieve\_rerank\_simple\_wikipedia.ipynb) ]: This script uses the smaller [Simple English Wikipedia](https://simple.wikipedia.org/wiki/Main\_Page) as document collection to provide answers to user questions / search queries. First, we split all Wikipedia articles into paragraphs and encode them with a bi-encoder. If a new query / question is entered, it is encoded by the same bi-encoder and the paragraphs with the highest cosine-similarity are retrieved (see [semantic search](../semantic-search/README.html)). Next, the retrieved candidates are scored by a Cross-Encoder re-ranker and the 5 passages with the highest score from the Cross-Encoder are presented to the user.

•

\*\*[in\_document\_search\_crossencoder.py](https://github.com/UKPLab/sentence-transformers/tree/m aster/examples/applications/retrieve\_rerank/in\_document\_search\_crossencoder.py):\*\* If you only have a small set of paragraphs, we don't do the retrieval stage. This is for example the case if you want to perform search within a single document. In this example, we take the Wikipedia article about Europe and split it into paragraphs. Then, the search query / question and all paragraphs are scored using the Cross-Encoder re-ranker. The most relevant passages for the query are returned.

```
## Pre-trained Bi-Encoders (Retrieval) if •
```

The bi-encoder produces embeddings independently for your paragraphs and for your search queries. You can use it like this:

```
from sentence_transformers import SentenceTransformer

model = SentenceTransformer("multi-qa-mpnet-base-dot-v1")

docs = [

"My first paragraph. That contains information",

"Python is a programming language.",

]

document_embeddings = model.encode(docs)

query = "What is Python?"

query_embedding = model.encode(query)
```

For more details how to compare the embeddings, see [semantic search](../semantic-search/README.html).

We provide pre-trained models based on:

\* \*\*MS MARCO:\*\* 500k real user queries from Bing search engine. See [MS MARCO models](../../docs/pretrained-models/msmarco-v3.html)

## Pre-trained Cross-Encoders (Re-Ranker) if •

For pre-trained Cross Encoder models, see: [MS MARCO Cross-

Encoders](../../docs/pretrained-models/ce-msmarco.html)

[ Previous](../semantic-search/README.html "Semantic Search") [Next ](../clustering/README.html "Clustering")
